

# Short-period planets of intermediate-mass stars

*Fike W. Guenther*

*Thüringer Landessternwarte Tautenburg  
and the CoRoT team*

# Two species of planets

- > Planets of  $M \sim 10 M_{\text{Earth}}$  with densities of  $1\text{-}10 \text{ g cm}^{-3}$
- > planets with  $M > 1 M_{\text{Jupiter}}$  relation between mass and density

Rauer et al. 2014

## A highlight was the discovery of CoRoT-20b:

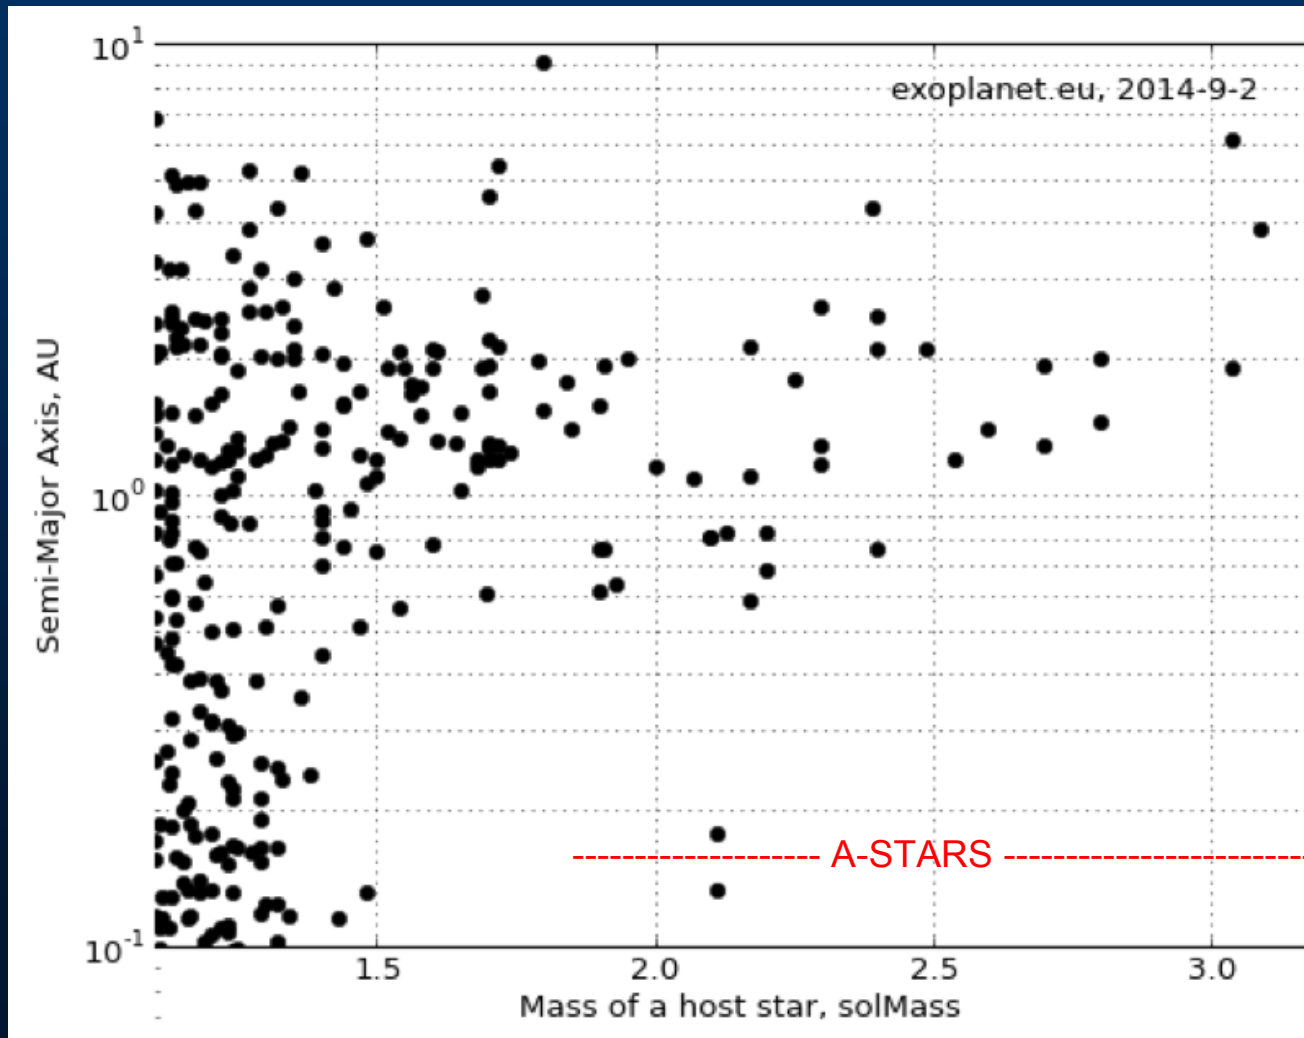

**A planet  $4.24 \pm 0.23 M_{\text{Jup}}$  ( $=1350 M_{\text{Earth}}$ ), with a core of 680 to  $1040 M_{\text{Earth}}$  (between 55 and 77% of its total mass is the core), and a density  $8.87 \pm 1.10 \text{ gcm}^{-3}$  that is orbiting a star of  $1.14 \pm 0.08 M_{\text{sun}}$  (Deleuil et al. 2012)**

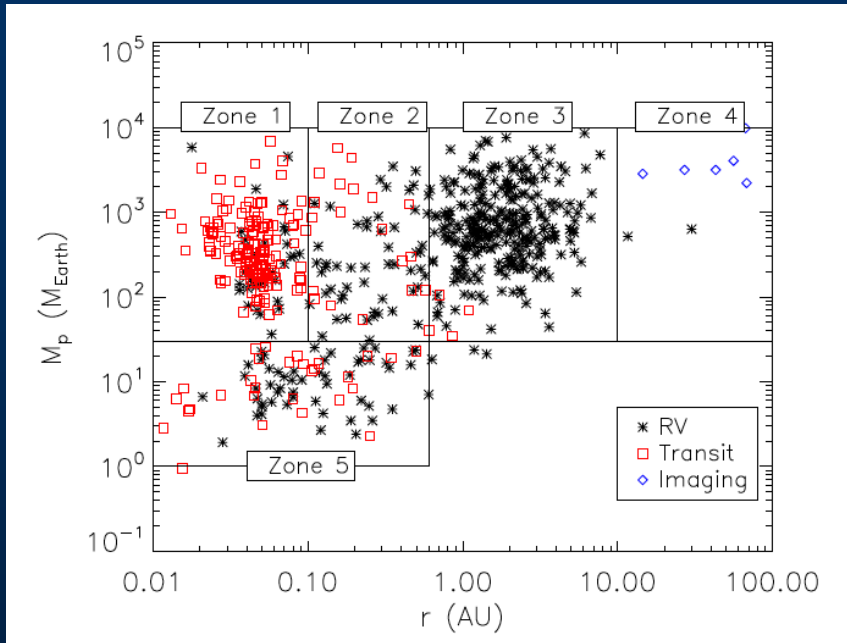

# Surveys of giant stars show that massive stars also have a lot of massive planets.

# No (massive) planets with 0.7 AU for stars with $M > 1.4 M_{\text{sun}}$

# Yasuhiro Hasegawa and Ralph E. Pudritz 2014

## Why is it interesting to search for short-period planets of intermediate-mass stars?

- **FORMATION:** Theory predicts that stars more massive than the sun should have a higher frequency of planets. However, the life-time of the disk is short ( $t_{\text{disk}}=2.5$  Myrs for  $M^*\sim 1.0 M_{\text{sun}}$ ,  $t_{\text{disk}}=1.2$  Myrs for  $M^*>1.3 M_{\text{sun}}$ ).

----> Is there enough time for the planets to form and migrate inwards?

- **EVOLUTION:** Close-in planets of intermediate-mass stars would be engulfed when the star becomes a giant: How does this affect stellar evolution?
- **EVOLUTION:** An A5V star is in the optical regime 14 times brighter than the sun! How does this affect the atmosphere of the planet?

# CoRoT

(Convection, Rotation et Transites planétaires)

Dec 27, 2006 to Nov 2, 2012

mass: 605 kg

Apertures of the telescope: 27 cm

Field of view: 4.5, 2.3 Square degrees per field

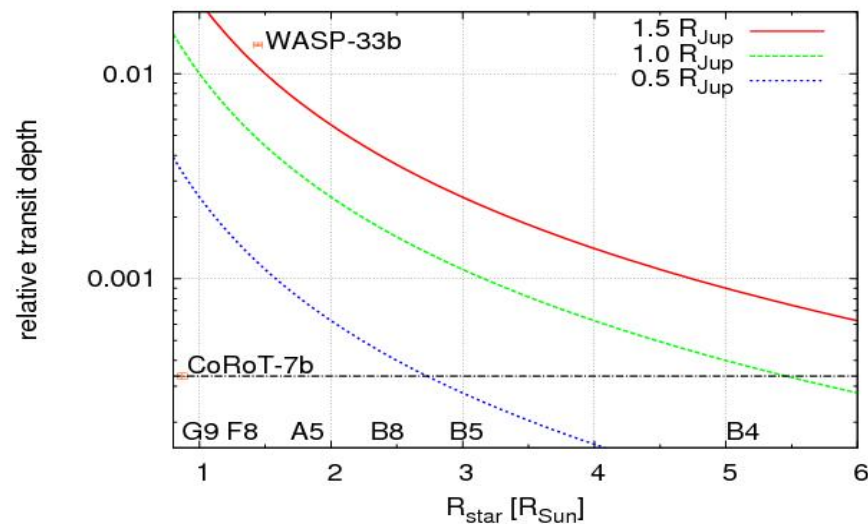

# Harvest of CoRoT

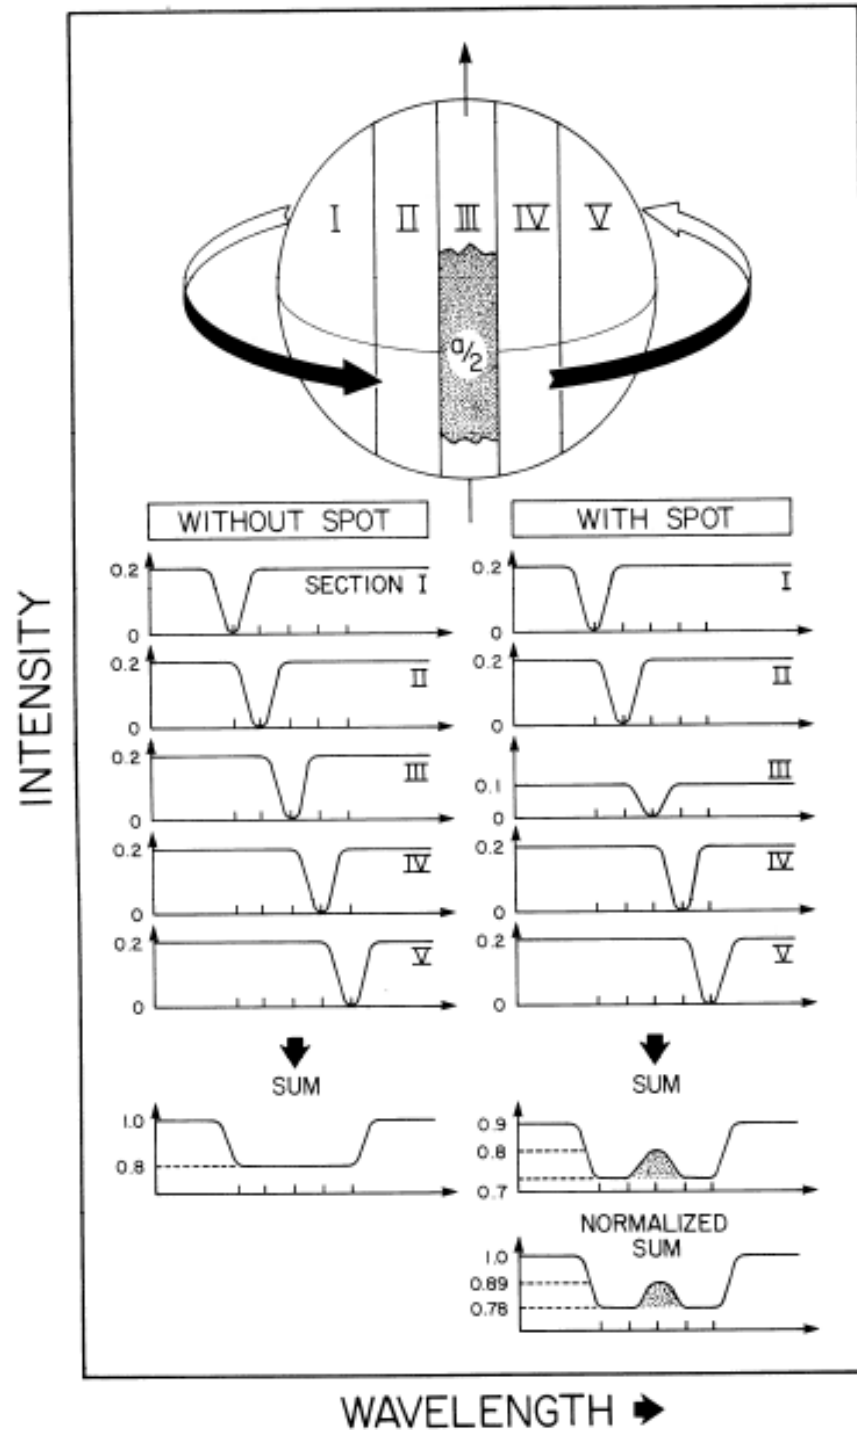

- 163664 stars with  $m_v=11-16.5$  observed.
- 26 fields, with 58 square degrees in total observed.
- Shortest run 21 days, longest 152 days.
- Noise level 100, 150, 250, ppm in 3h at  $m_v=12, 13, 14$ .
- 3-colour light-curves for  $m_v > 15$ .
- 60% of all planets with 2-4  $R_{\text{Earth}}$  detected for stars of  $m_v=14$ .
- **3900 stars with transits; 500 in the planetary regime.**
- Follow-up: > 200 nights for photometric FU (mostly 1-2m class telescopes); > 350 nights for RV FU (mostly 2-4 m class); 280 cases fully resolved: 19% diluted binaries; 27% undiluted binaries.
- 35 fully characterized planets.
- Unsolved cases: 20% too faint, 10% ephemeris lost,
- ---> **20% rotate too fast !**

# The planets of intermediate-mass stars should already be in the candidate list!

- **Candidates (from Santern), size of the dots indicates brightness of the star**
- **CoRoT has the capability to detect hot Jupiters of stars as early as B4V, and planets of 2  $R_{\text{Earth}}$  around G-type stars**

# Detecting planets in rapidly rotating stars using time resolved spectroscopy

Volgt & Penrod 1983

**HD15082b (WASP-33b):**  
**Time series of the residual**  
**average spectral line: the**  
**“white” line from the middle**  
**right to the upper left is the**  
**signature of the planet (NOT,**  
**McDO, TLS-data)**

**A survey for short period transiting  
planets of stars more massive than the  
sun using the CoRoT satellite**

# Excluding false-positives

- Detailed modelling of the (multi-colour) LCs
  - Photometry/low-resolution spectroscopy to exclude giant stars (consistence checks)
  - Seeing-limited observation in and out of transit
- > AO-imaging**
- > HR IR-spectroscopy**
- Radial-velocity observations

**AO-imaging:**

**Expectation:** <10% of the stars should have a companions.

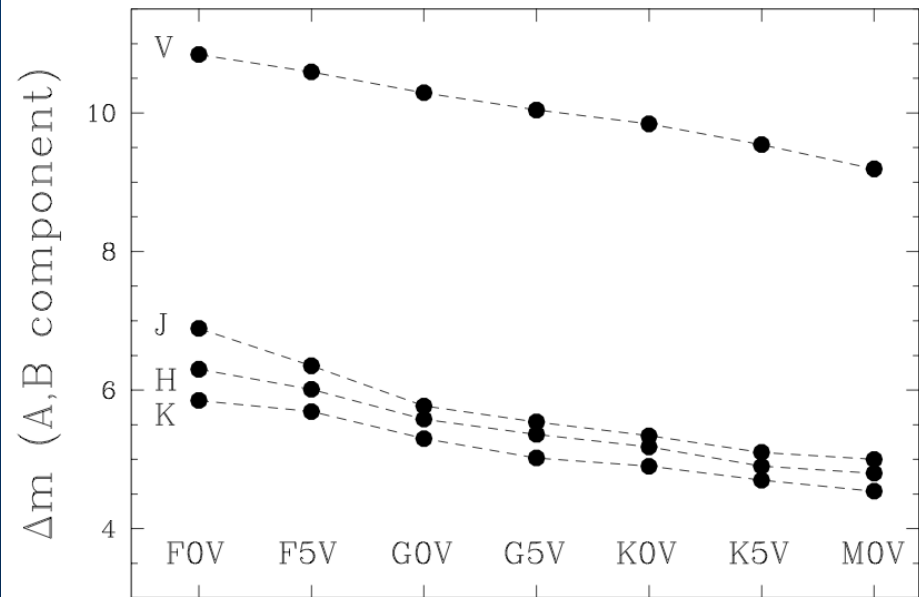

**Result: 30-40%** have one!

Scale: 1 arcsec

# High resolution near-infrared spectroscopy to exclude companions

- The brightness difference between a solar-like star and a potential FP is much smaller in the IR than in the optical (upper Fig.: brightness difference between a primary and a secondary that mimics a transiting Jupiter-like planet).
- The CO-lines become stronger for cooler stars.

spec. type A-component

**After the detailed light-curve analysis (consistence checks) and seeing limited observations, the remaining false-positives typically look like this!**

**Companions to stars within 10pc  
(Dietrich et al. 2012)**

## Sub-stellar companions orbiting stars with $M > 1.1 M_{\text{sun}}$ discovered by CoRoT

Name	$M_{\text{star}}$	Period[d]	Rplanet [ $R_{\text{Jup}}$ ]	Mplanet [ $M_{\text{Jup}}$ ]	Density [ $\text{g cm}^{-3}$ ]
CoRoT-3b	$1.37 \pm 0.09$	4.3	$1.01 \pm 0.07$	$21.7 \pm 1.0$	$26.4 \pm 5.6$

# Transit light-curve obtained by CoRoT

# Seeing limited imaging with 1-m WISE& IAC 0.8 m telescopes: Transit is detected on source!

# AO-imaging

- PISCES@LBT in J and K-band
- CoRoT LC shows transit with period 5.6d,  $DF/F=0.9\%$
- $V=13.055\pm 0.066$  --> we have to exclude stars of  $V=18.2$  mag
- PISCES observations show two additional stars:  
star1: 1.96 arcsec distance,  $J=15.7\pm 0.1$ ,  $K=16.2\pm 0.1$  --> fainter than  $V=18.2$   
star2: 3.46 arcsec distance,  $J=17.1\pm 0.1$ ,  $K=16.8\pm 0.1$  --> fainter than  $V=18.2$

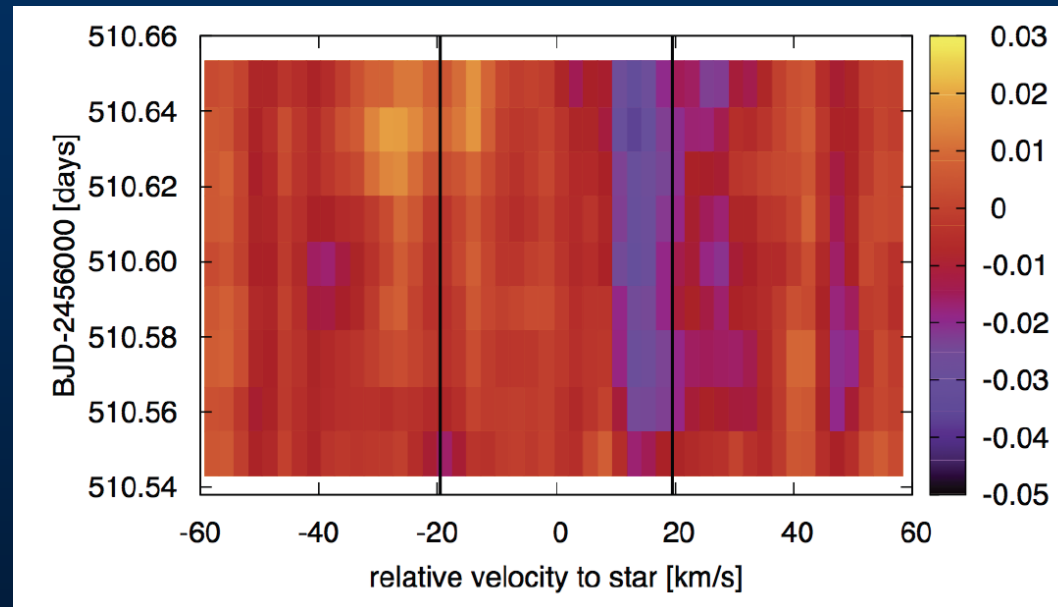

# RV-measurements during the transit

# Time-resolved spectroscopy of CoRoT-35b: The planet has a polar orbit!

## Statistics of the planet discoveries:

- **0-5% are orbiting stars of 1.3-3.2  $M_{\text{sun}}$  (“A-stars”)**
- **30-32% are orbiting stars of 1.1 to 1.3  $M_{\text{sun}}$  (“F-stars”)**
- **50-54% are orbiting stars of 0.9- 1.1  $M_{\text{sun}}$  (“G-stars”)**
- **13-16% are orbiting stars of 0.4-0.8  $M_{\text{sun}}$  (“K-stars”)**

## The sample:

- **16% are stars of 1.3-3.2  $M_{\text{sun}}$  (“A-stars”)**
- **35% are stars of 1.1 to 1.3  $M_{\text{sun}}$  (“F-stars”)**
- **15% are stars of 0.9- 1.1  $M_{\text{sun}}$  (“G-stars”)**
- **5% are stars of 0.4-0.8  $M_{\text{sun}}$  (“K-stars”)**

## Results:

- > We have surveyed 19 candidates with spectral-types B5V to F8V.**
- > Although 25% of the CoRoT stars have masses in the range from 1.5 and 3.2  $M_{\text{sun}}$ , we found only 1-2 that have sub-stellar companions.**
- > We do not find the same rapid increase of the frequency of massive planets for close-in planets as it is found for planets at large orbital distance (RV-surveys of giant stars).**
- > The number of planets found for stars in the mass-range between 1.1 and 1.5  $M_{\text{sun}}$  is within the errors the same as for solar-like stars.**

# Continue survey using Kepler 2 mission

- 300 ppm at V=14 in 3 hours (same as CoRoT)
- 10 fields, each observed for 80 days
- 1000 square degrees in total (17 times better than CoRoT).
- Field 0: 2014 Apr 30
- Field 1: 2014 Jul 22
- Field 2: 2014 Oct 14
- Field 3: 2015 Jan 5

**Thank you**

# A short look at Kepler data

- 2011: based on stellar statistics Morton & Johnson estimate the FP-rate to be <10%.
- 2012: Santerne et al. obtain RV-measurements of 46 candidates with transit depth >0.4% and periods of less than 26d, from which they derive a FP-rate of 46%.
- 2012: Colón et al. obtain multicolour transit photometry 4 candidates with  $R < 6 R_{\text{Earth}}$ , two candidates are FP. The probability of identifying two false positives out of a sample of four targets is less than 1%, assuming an overall false positive rate for Kepler planet candidates of 10%.
- 2012: Lillo-Box et al. observes 98 candidates using lucky imaging. In 41.8% of the candidates, they find at least one additional star within 6 arcsec. In 17% there is at least one star within 2 arcsec. Of these, 42% of the same i-z colour as a physical companion.
- 2014: Gilliland et al. observes 23 cool, low mass planet candidates observed with HST. 6 have physical companions. This is 3 times higher than expected.

**The first known transiting planet of a star  
with  $M_* > 1.4 M_{\text{sun}}$  is HD15082b (WASP-33b)**
